Quanto ci mette un ordine ad arrivare, viene modellato con probabilità.

Multi-Stream Lehmer RNGs

- Typical DES models have many stochastic components
- Want a unique source of randomness for each component
- One (poor) option: multiple RNGs
- Better option: one RNG with multiple "streams" of random numbers
 - one stream per stochastic component

We will partition output from our Lehmer RNG into multiple streams

Prof. Vittoria de Nitto Personè

2

2

Il generatore è sempre di Lehmer, con più "streams". Non posso usare lo stesso flusso per arrivi e servizi, anche perchè creerei correlazione tra due processi che sono slegati. Devo usare un flusso separato per ogni componente (un pezzo della ruota per arrivi, un altro per servizi). Devo cercare di capire come usare 'tale ruota' per diverse componenti stocastiche che devono rimanere indipendenti. E' alla base del multi-stream.

Arrival and service processes

- two stochastic components: arrival and service
- allocate a different state variable to each

```
double GetService(void)
{
    return Uniform(1.0, 2.0);
}
```

```
double GetService(void)
{
    double s;
    static long x = 12345;
    PutSeed(x);
    s = Uniform(1.0, 2.0);
    GetSeed(&x);
    return (s);
}
```

solo la prima volta!

- x represents the current state of the service process

lo stato è l'ultimo valore generato, in pratica quando richiamo la funzione questa riparte dall'ultimo valore estratto e 'procede'.

Prof. Vittoria de Nitto Personè

3

3

Arrival and service processes

- Arrival should have its own static variable, initialized differently

```
double GetArrival(void)
{
    static double arrival = START;
    arrival += Exponential(2.0);
    return (arrival);
}
```

```
double GetArrival(void)
{
    static double arrival = START;
    static long x = 54321; cambio seme
    PutSeed(x);
    arrival += Exponential(2.0);
    GetSeed(&x);
    return (arrival);
}
```

solo la prima volta!

- x represents the current state of arrival process

Prof. Vittoria de Nitto Personè

4

4

The Modified Arrival and Service Processes

- As modified, arrival and service times are drawn from different streams of random numbers
- Provided the streams don't overlap → the processes are *uncoupled*
- Execution time cost is negligible

Prof. Vittoria de Nitto Personè

5

5

- Potential problem: assignment of initial seeds to *produce disjoint streams*
- If states are picked at whim, no guarantee of disjoint streams
- Some initial states may only be a few calls to Random apart!

Prof. Vittoria de Nitto Personè

6

Jump Multipliers

- We will develop a multi-stream version of rng

Theorem

Given $g(x) = ax \bmod m$ and integer j ($1 < j < m-1$)

jump function: $g^j(x) = (a^j \bmod m)x \bmod m$

jump multiplier: $a^j \bmod m$

If $g(\cdot)$ generates x_0, x_1, x_2, \dots then $g^j(\cdot)$ generates x_0, x_j, x_{2j}, \dots
mi sposto su sequenze di lunghezza 'j'.

- This theorem is the key to creating streams

Prof. Vittoria de Nitto Personè

7

7

Example 1

- If $m = 31$, $a = 3$ and $j = 6$, the jump multiplier is

$$a^j \bmod m = 3^6 \bmod 31 = 16$$

- If $x_0 = 1$, then $g(x) = 3x \bmod 31$ generates:

1, 3, 9, 27, 19, 26, 16, 17, 20, 29, 25, 13, 8, 24, 10, 30, 28,
22, 4, 12, 5, 15, 14, 11, 2, 6, 18, 23, 7, 21, 1, ...

- The jump function $g^6(x) = 16x \bmod 31$ generates:

1, 16, 8, 4, 2, 1, ...

e' come avere sei generatori disgiunti, anche se in realtà ne sto usando uno!
Questa tecnica è migliore di usare 6 generatori di Lehmer.

Prof. Vittoria de Nitto Personè

8

8

Example 1

- If $m = 31$, $a = 3$ and $j = 6$, the jump multiplier is

$$a^j \bmod m = 3^6 \bmod 31 = 16$$

- If $x_0 = 1$, then $g(x) = 3x \bmod 31$ generates:

1, 3, 9, 27, 19, 26, 16, 17, 20, 29, 25, 13, 8, 24, 10, 30, 28,
22, 4, 12, 5, 15, 14, 11, 2, 6, 18, 23, 7, 21, 1, . . .

- The jump function $g^6(x) = 16x \bmod 31$ generates:

1, 16, 8, 4, 2, 1, . . .

- I.e., the first sequence is x_0, x_1, x_2, \dots ; the second is x_0, x_6, x_{12}, \dots

Prof. Vittoria de Nitto Personè

9

9

Example 1

$$m = 31, a = 3, x_0 = 1$$

1, 3, 9, 27, 19, 26, 16, 17, 20, 29, 25, 13, 8, 24, 10, 30, 28,
22, 4, 12, 5, 15, 14, 11, 2, 6, 18, 23, 7, 21, 1, . . .

$x_0 =$ 1, 3, 9, 27, 19, 26,
 $x_6 =$ 16, 17, 20, 29, 25, 13,
 $x_{12} =$ 8, 24, 10, 30, 28, 22,
 $x_{18} =$ 4, 12, 5, 15, 14, 11,
 $x_{24} =$ 2, 6, 18, 23, 7, 21,

Devono però bastarmi questi numeri!

- The jump function $g^6(x) = 16x \bmod 31$ generates:

1, 16, 8, 4, 2, 1, . . .

Prof. Vittoria de Nitto Personè

10

10

Using the jump function

- First, compute the jump multiplier $a^j \bmod m$ (one time cost)
 - Then, $g^j(\cdot)$ allows jumping from x_0 to x_j to x_{2j} to ...
 - The user supplies ONE initial seed uso un seed e poi applico la funzione salto.
 - If j is chosen well, $g^j(\cdot)$ can “plant” additional initial seeds
 - Each planted seed corresponds to a different stream
 - Each planted seed is *separated* by j calls to Random
- ogni seed dista 'j' dall'altro.

Prof. Vittoria de Nitto Personè

11

11

voglio dividere la ruota in 4 flussi separati, con generatore che
'salta' da un flusso all'altro, cioè tra i vari $x(i)$, che sono pezzi disgiunti.

Example 2: 4-stream sequence

Prof. Vittoria de Nitto Personè

12

12

An appropriate jump multiplier

- Consider $256 = 2^8$ different streams of random numbers
- Partition the RNG output sequence into 256 disjoint subsequences of equal length
- Find the largest $j < 2^{31}/2^8 = 2^{23}$ such that the jump multiplier is modulus-compatible
- $g^j(x) = (48271^j \bmod m)x \bmod m$ can be implemented via algorithm 1 (2.2.1 in the book)
- Then $g^j(x)$ can be used to plant the other 255 initial seeds
- Possibility of stream overlap is minimized (though not eliminated!)

Algorithm 1

```

t = a * (x % q) - r * (x / q);      /* t = γ(x) */
if (t > 0)
    return (t);                    /* δ(x) = 0 */
else
    return (t + m);                 /* δ(x) = 1 */

```

Prof. Vittoria de Nitto Personè

13

13

Maximal Modulus-Compatible Jump Multipliers

- Maximal jump multiplier:** maximize the distance between streams, $a^j \bmod m$ where j is the largest integer less than $\lfloor m/s \rfloor$, s number of streams, such that $a^j \bmod m$ is modulus compatible

$$a = 48271 \quad m = 2^{31} - 1$$

Example 2 (cont.)

# of streams s	lunghezza sottosequenza $\lfloor m/s \rfloor$	intero più grande ma minore di m/s jump size j	jump multiplier $a^j \bmod m$
1024	2097151	2082675	97070
512	4194303	4170283	44857
standard 256	8388607	8367782	22925
128	16777215	16775552	40509

Prof. Vittoria de Nitto Personè

14

14

Library rngs

- Upward-compatible multi-stream replacement for rng
- Provides 256 streams, indexed 0 to 255 (0 is the default)
- Only one stream is active at any time
- 6 available functions:
 - `Random(void)`: to use the standard Lehmer generator
 - `PutSeed(long x)`: to set the state of the active stream
 - `GetSeed(long *x)`: to obtain the state of the active stream
 - `TestRandom(void)`: to test the implementation correctness
 - `SelectStream(int s)`: to define the active stream da dove 'partire'.
 - `PlantSeeds(long x)`: "plants" one seed per stream
a partire dal primo seme pianta tutti gli altri
